

Multiple Myeloma Research Review™

Making Education Easy

Issue 31 – 2019

In this issue:

- Increased novel agent access in NZ improved MM survival
- Impact of acquired del(17p) in MM
- Pomalidomide-based regimens for relapsed/refractory MM
- Daratumumab, lenalidomide + dexamethasone for untreated myeloma
- Carfilzomib or bortezomib, + melphalan-prednisone, for transplant-ineligible new MM
- Single-agent daratumumab in very advanced relapsed/refractory MM
- Carfilzomib vs. bortezomib, + dexamethasone, in relapsed/refractory MM
- Impact of prior monoclonal gammopathy diagnosis on MM outcomes

Abbreviations used in this issue

CR = complete response
HR = hazard ratio
MGUS = monoclonal gammopathy of undetermined significance
MM = multiple myeloma
MRD = minimal residual disease
ORR = overall response rate
OS = overall survival
PFS = progression-free survival
PI = proteasome inhibitor
RCT = randomised controlled trial

new zealand

Myeloma NZ is a new foundation in NZ to provide a deeper level of support for those who affected by multiple myeloma. If patients or their loved one have been diagnosed with multiple myeloma, Myeloma NZ can help them learn about treatment options and point them to information and services to help them cope with the disease. www.multiplemyeloma.org.nz/

New Zealand
Society for Oncology
Conference 2019

25 – 26 October, Wellington www.nzsoncology.org.nz

Welcome to issue 31 of Multiple Myeloma Research Review.

In 2011, frontline bortezomib became available and thalidomide availability was expanded in NZ, and the impact this has had on MM survival is the focus of the first paper in this issue. Results from two phase 3 trials in transplant-ineligible patients with newly diagnosed MM are also included: the encouraging ongoing MAIA trial, which is investigating the addition of the monoclonal immunotherapeutic daratumumab to standard lenalidomide/dexamethasone; and the CLARION trial, which has compared carfilzomib versus bortezomib, both combined with melphalan and prednisone, but has failed to deliver promising results, possibly due to limitations of the trial's design. This issue concludes with research reporting on the impact of pre-existing monoclonal gammopathies on MM outcomes.

We hope you enjoy this issue, and we welcome your comments and feedback.

Kind regards,

Dr David Simpson

davidsimpson@researchreview.co.nz

Impact of increased access to novel agents on the survival of multiple myeloma patients treated at a single New Zealand centre

Authors: Hock BD et al.

Summary: The impact of changes in novel agent usage on MM survival was reported for a retrospective cohort of real-world patients treated at Christchurch Hospital. Patients treated during 2000–2009 (n=237) were compared with those treated during 2011–2017 (n=343); frontline bortezomib became available and thalidomide availability was expanded in 2011. Compared with patients treated in the earlier cohort, those treated in the later cohort were significantly more likely to be treated with novel agents (85% vs. 55%) and had longer median OS duration (56 vs. 44 months) and a greater proportion of patients aged <70 years underwent autologous stem-cell transplantation (74% vs. 49%). In older patients, those treated in the later cohort had significantly longer median OS duration (28 vs. 17 months), but the 5-year relative survival rate remained <50%. In younger patients, those from the later cohort also had significantly increased initial OS duration with the survival curves converging at 5 years. While OS durations did not differ significantly between cohorts for patients who underwent autologous stem-cell transplantation, their median PFS duration was significantly longer in the later cohort (40 vs. 20 months).

Comment (KR): This Christchurch single-centre study adds to the real-world data from the two other recent papers that looked at the total NZ myeloma population. This was the Dunedin study (Sneyd *et al.*) and the Burden of disease study by Milne and Chan now published in *Br J Haematol*. The results are interesting in that although the median OS of the whole cohort study has improved, this does not translate into an improved OS in the post- (later) cohort transplant group. The use of novel agents seems to have impact on the increased proportion of patients getting to transplant in the post-cohort group and 74% is a very good number, which hopefully will translate to improved survival with a longer follow-up.

[Abstract](#)

Impact of acquired del(17p) in multiple myeloma

Authors: Lakshman A et al.

Summary: This was a comparison of 76 patients with MM without del(17p) at diagnosis but with subsequent acquisition of this mutation (at median of 35.6 months and after a median of two lines of therapy) versus 152 del(17p)-negative control patients without later acquisition at comparable timepoints. Compared with controls, patients who acquired del(17p) had shorter median PFS and OS durations (30.1 vs. 23.0 months [p=0.032] and 106.1 vs. 68.2 months [p<0.001], respectively). The respective median PFS and OS durations following del(17p) detection were 5.4 and 18.1 months. Predictors of del(17p) acquisition were an elevated LDH level (odds ratio 3.69 [95% CI 1.11, 12.24]) and presence of t(4;14) mutation or any high-risk translocation (2.66 [1.09, 6.48] and 2.23 [1.00, 4.95], respectively) at diagnosis. After del(17p) detection, shorter OS was predicted by a high rate of plasma cell proliferation (HR 2.28 [95% CI 1.31, 3.96]).

Comment (KR): This small study illustrates the adverse effect that acquisition of a del(17p) has on survival in myeloma. It is not a common practice in NZ to revisit FISH (fluorescence *in situ* hybridisation) studies at progression of disease. This study also shows that high risk features tend to co-aggregate to give a double hit scenario that does not bode well.

[Abstract](#)

Pomalidomide-based regimens for treatment of relapsed and relapsed/refractory multiple myeloma

Authors: Mushtaq A et al.

Summary: This was a systematic review and meta-analysis of 35 phase 2 and 3 clinical trials (n=4623) reporting outcomes for different pomalidomide regimens for relapsed or refractory MM. The ORR for all 2- and 3-drug pomalidomide regimens was 47.1%. For the most frequently evaluated regimen of pomalidomide plus low-dose dexamethasone, the ORR was 35.7%, PFS duration was 6.1 months and OS duration was 14.37 months. The pooled ORR for triplet regimens was 61.9%. The respective ORRs and PFS durations for bortezomib, pomalidomide plus low-dose dexamethasone were 83.5% and 15.7 months, for carfilzomib, pomalidomide plus low-dose dexamethasone they were 77.1% and 15.3 months, and for pomalidomide, low-dose dexamethasone plus cyclophosphamide they were 59.4% and 9.5 months. The ORR for pomalidomide, low-dose dexamethasone plus bendamustine was 74.2%, for pomalidomide, dexamethasone plus daratumumab it was 64.5% and for pomalidomide, low-dose dexamethasone plus doxorubicin it was 32%. The main adverse events were myelosuppressive, with respective mean incidences of grade ≥ 3 neutropenia, anaemia and thrombocytopenia of 47.6%, 26.5% and 20.8%. Grade ≥ 3 nonhaematological adverse events were infections (29.1%), pneumonia (13.8%) and fatigue (10%).

Comment (KR): This is a very large pooled analysis of studies looking at the synergistic activity of pomalidomide with Pls. Personal experience from the time when carfilzomib was available to be used in a compassionate setting has shown that this drug used with pomalidomide gives excellent responses. In Australia, the PBAC does not currently allow the use of doublet regimens in the relapse setting. In NZ, we are now unable to use the combinations either, and we need better access to effective drugs for relapsed disease.

Daratumumab plus lenalidomide and dexamethasone for untreated myeloma

Authors: Facon T et al., for the MAIA Trial Investigators

Summary: The phase 3 MAIA trial randomised patients with newly diagnosed MM to RD (lenalidomide plus dexamethasone) with (n=368) or without (n=369) daratumumab until disease progression or unacceptable toxicity. This interim analysis after a median follow-up of 28 months found that compared with RD, daratumumab plus RD was associated with a significantly lower proportion of participants who experienced disease progression or death (26.4% vs. 38.8%; HR 0.56 [95% CI 0.43, 0.73]), a greater CR or better rate (47.6% vs. 24.9% [$p < 0.001$]) and a greater proportion of participants below the threshold for MRD (24.2% vs. 7.3%). Grade 3-4 adverse event rates were higher in the daratumumab group, with the most common being neutropenia (50% vs. 35.3% for RD), lymphopenia (15.1% vs. 10.7%) and pneumonia (13.7% vs. 7.9%).

Comment (KR): The MAIA study was presented by Facon at the last ASH meeting in a late-breaker session and is now published. The results in this nontransplant-eligible group certainly show a significant increase in CR over the controls and also an improved PFS. One minor criticism would be that RVD is a more potent comparator arm than RD. Never the less the study highlights the improvement in response that daratumumab offers over standard therapy in the upfront setting.

Comment (DS): Daratumumab continues to do for myeloma what rituximab did for B-cell lymphomas with improved depth of response and better PFS whenever it is added. The MRD-negative rate was increased to nearly 25% in this nontransplant cohort. There was a small price to pay with increased infections and neutropenia. Infusion reactions were common but not often severe. The frequent infusions require commitment, but this will be less of an issue if subcutaneous daratumumab is used. While these results are good, it is likely that adding a PI would give even deeper responses. So the question is not whether to add daratumumab, but to add it to what?

STAYING POWER^{1†}

Revlimid[®]
(lenalidomide) capsules

Think FIRST[†]

Continuous REVLIMID/dex in transplant ineligible ndMM^{2,3}

Final analysis:
67 months¹

The FIRST trial demonstrated that Continuous REVLIMID/dex (Rd) significantly improved survival outcomes vs. fixed-duration MPT in transplant-ineligible ndMM^{1,3,4}

Continuous Rd provided patients with:

- ✓ 5.8 years median time to next therapy in patients achieving at least a VGPR¹
- ✓ 10 months longer median OS vs. MPT¹

*FIRST: Frontline Investigation of Revlimid and dexamethasone vs. Standard Thalidomide trial. Continuous: treatment until disease progression or intolerance; dex: dexamethasone; MPT: melphalan, prednisone, thalidomide; ndMM: newly diagnosed multiple myeloma; OS: overall survival; Rd: REVLIMID/dexamethasone; VGPR: very good partial response. Before prescribing REVLIMID (lenalidomide) please refer to following page. TAPS No. NA 11216

Carfilzomib or bortezomib with melphalan-prednisone for transplant-ineligible patients with newly diagnosed multiple myeloma

Authors: Facon T et al.

Summary: The phase 3 open-label CLARION trial randomised transplant-ineligible patients with newly diagnosed MM to receive nine 42-day cycles of KMP (carfilzomib, melphalan, prednisone; n=478) or VMP (bortezomib, melphalan, prednisone; n=477). No significant difference was seen between the KMP versus VMP arms for any of the endpoints, including PFS (22.3 vs. 22.1 months; HR 0.906 [95% CI 0.746, 1.101]) and ORR (84.3% vs. 78.8% [p=0.218]); grade ≥3 adverse event rates were also similar (74.7% vs. 76.2%).

Comment (KR): The CLARION study was a very large study that also involved several NZ centres. The twice-weekly infusions were a challenge and the cardiac and hypertension side effects have to be carefully monitored. The results are disappointing because there was no improvement in PFS despite the intensive treatment. Regimens such as KRd have been shown to improve CR rates, but carfilzomib has not made an impact in this transplant-ineligible group when compared with VMP.

Comment (DS): The ENDEAVOUR trial (also reviewed in this issue) clearly showed that carfilzomib was better than bortezomib, so it was a surprise that the CLARION trial did not show the same superiority. The dose of carfilzomib was lower in the CLARION trial, but I think the real difference was in the way the PIs were given. In both arms, six of the eight doses of drug were administered with no concomitant steroid or cytotoxic agent, and we know that PIs are not very effective as monotherapy. This study is a good example of how poor trial design using empirically derived therapy can set back drug development.

Single-agent daratumumab in very advanced relapsed and refractory multiple myeloma patients

Authors: Jullien M et al.

Summary: Outcomes for a series of 41 patients with relapsed or refractory MM treated with single-agent daratumumab from a single centre and outside of clinical trials were reported in the retrospective study. The patients had received a median number of four prior therapies and had been previously received PI and immunomodulatory agents. Most patients were high-risk, including 24% with del17p or t(4,14), 31% with extramedullary disease and 12% with circulating plasmacytosis at the time daratumumab was started. The ORR for these patients was 24%, including a very good partial response or better rate of 5%. All patients relapsed after median follow-up of 6.5 months with a median PFS duration of 1.9 months. At the time of disease progression, 44% of patients had not received subsequent therapy. Median OS duration was 6.5 months. There were no new safety signal detected.

Comment (DS): Daratumumab is an effective agent in myeloma; however, this real-life single-centre experience is sobering as the population mirrors the population who is eligible for the current compassionate access programme in NZ. The treatments were well tolerated but the response rate was lower than trial data with an ORR of 24%, although 39% had at least a minor response. All responses were short lived. The trials have a tail of durable responders and so this series likely reflects a publishing bias of a group who were disappointed in how their patients responded; however, we should not oversell the efficacy of single-agent treatment.

REVLIMID® is a funded medicine for Relapsed Refractory Multiple Myeloma, Special Authority criteria apply. REVLIMID® is an unfunded medicine for Newly Diagnosed Transplant Ineligible Multiple Myeloma, a prescription charge will apply. REVLIMID is a Prescription Medicine. Before prescribing REVLIMID (lenalidomide) please refer to the Data Sheet at www.medsafe.govt.nz/profs/Datasheet/r/revlimidcap.pdf

Teratogenic effects: Revlimid (lenalidomide) is structurally related to thalidomide. Thalidomide is a known human teratogen that causes severe life-threatening human birth defects. If lenalidomide is taken during pregnancy, it may cause birth defects or death to an unborn baby. Women should be advised to avoid pregnancy whilst taking Revlimid (lenalidomide), during dose interruptions and for 4 weeks after stopping the medicine.

Revlimid® (lenalidomide) Capsules Minimum Data Sheet. Indications: Revlimid is indicated for the treatment of patients with newly diagnosed multiple myeloma who are ineligible for autologous stem cell transplantation. Revlimid in combination with dexamethasone is indicated for the treatment of multiple myeloma patients whose disease has progressed after one therapy. **Contraindications and precautions:** (Pregnancy Risk Category X) – Pregnancy; women of childbearing potential unless all of the conditions of the i-access® Program are met; hypersensitivity to lenalidomide or excipients. To avoid the risk of foetal exposure, Revlimid is only available under a restricted distribution program (i-access®). **Other precautions:** Breast feeding. Second Primary Malignancies (SPMs): in clinical trials of Revlimid an imbalance in the incidence of SPMs between treated and control groups has been observed. The expected benefit of Revlimid and the risk of SPMs should be considered before initiating treatment; patients should be evaluated for SPMs before and during treatment. Myocardial infarction. Venous thromboembolism (predominantly deep vein thrombosis and pulmonary embolism) and arterial thromboembolism (predominantly myocardial infarction and cerebrovascular event). If patient experiences thromboembolic events, discontinue Revlimid treatment and start anticoagulant therapy, with treatment reinstitution at original dose once stable and depending upon a benefit-risk assessment. Anticoagulation therapy should then be continued during the course of Revlimid treatment. Neutropenia, thrombocytopenia (dose reduction may be required). Peripheral neuropathy. Tumour Lysis Syndrome (TLS) and Tumour Flare Reaction (TFR). Consider interruption or discontinuation of Revlimid for Grade 2-3 skin rash. Permanently discontinue Revlimid for angioedema, Grade 4 rash, exfoliative or bullous rash, or suspected Stevens-Johnson Syndrome (SJS), toxic epidermal necrolysis or drug reaction eosinophilia and system symptoms (DRESS). Patients with prior history of grade 4 rash associated with thalidomide should not receive Revlimid. Atrial fibrillation. Impaired thyroid function. Lactose intolerance. Hepatic disorders; monitoring recommended. Chronic Lymphocytic Leukaemia (CLL) and Revlimid: In a clinical trial of first-line treatment of patients with CLL, Revlimid was associated with increased risk of death - not recommended for use in CLL outside of controlled clinical trials. No experience in treating children and adolescents (0-18 years). Serious adverse events more common in patients greater than 65 years of age. Monitor renal function in patients with renal impairment; dosage adjustment may be required. **Interactions:** Use with caution with erythropoietic agents, hormone replacement therapy or other agents that increase the risk of thrombosis. Use with caution when coadministering with myelosuppressive agents. Oral contraceptive efficacy may be reduced during treatment. Efficacy of contraceptive steroids may be reduced during co-treatment with dexamethasone. Monitor warfarin concentration. Increased risk of rhabdomyolysis with statins. Adverse Drug Reactions (MM and MDS) VERY COMMON: pneumonia; bronchitis; bacterial, viral and fungal infections (including opportunistic infections); upper respiratory tract infection; neutropenias; thrombocytopenia; anaemia, leukopenias; decreased appetite; hypokalaemia; hyperglycaemia; hypocalcaemia; insomnia; depression; peripheral neuropathies (excluding motor neuropathy); dizziness; tremor; dysgeusia; headache; cataracts; blurred vision; venous thromboembolic events (predominantly deep vein thrombosis and pulmonary embolism); dyspnoea; epistaxis; diarrhoea; vomiting; nausea; constipation; abdominal pain; dyspepsia; rash; pruritus, dry skin; hyperhidrosis; musculoskeletal and connective tissue pain and discomfort; bone pain; muscle spasms; arthralgia; myalgia; renal failure (including acute); pyrexia; oedema (including peripheral); asthenia; influenza-like illness syndrome (including pyrexia, cough, rhinitis, myalgia, musculoskeletal pain, headache and rigors); fatigue; weight decreased COMMON: sepsis, sinusitis, hypothyroidism; febrile neutropenia; pancytopenia; dehydration; hypomagnesaemia; iron overload; hypocalcaemia; hypophosphataemia; diabetes mellitus; hyperglycaemia; hyponatraemia; gout; lethargy; syncope; cerebrovascular accident; myocardial infarction (including acute); atrial fibrillation; tachycardia; cardiac failure (including congestive); hypertension; hypotension; haematoma; respiratory distress; dry mouth; toothache; abnormal liver function tests; cholestasis; erythema; muscular weakness; chest pain; fall; contusion; squamous cell carcinoma POST-MARKETING: SJS; toxic epidermal necrolysis; TLS; TFR; hepatic failure (incl. acute); hepatitis toxic; cytolytic hepatitis; cholestatic hepatitis; mixed cytolytic/cholestatic hepatitis; acute graft-versus-host disease (after allogeneic transplant); pancreatitis; pneumonitis; hyperthyroidism; viral reactivation (such as hepatitis B virus or herpes zoster); solid organ transplant rejection; DRESS. **Dosage and administration:** Multiple myeloma (MM): recommended starting dose is 25 mg orally once daily on days 1-21 of repeated 28-day cycles; for recommended dose of dexamethasone please see Data Sheet. In MM dosing is continued or modified based upon clinical and laboratory findings, and to manage grade 3 or 4 neutropenia or thrombocytopenia, or other grade 3 or 4 toxicities judged to be related to Revlimid. Dose adjustments are recommended at the start of therapy for patients with moderate or severe impaired renal function, or end stage renal disease (refer to Dosage and Administration in Data Sheet). Revlimid (5 mg, 10 mg, 15 mg and 25 mg capsules) should be taken at about the same time each day swallowed whole (not opened, broken or chewed), preferably with water one hour before or two hours after food. Please review the Revlimid® (lenalidomide) Data Sheet for the full dosage and administration recommendations.

Carfilzomib-dexamethasone versus bortezomib-dexamethasone in relapsed or refractory multiple myeloma

Authors: Orlowski RZ et al.

Summary: Updated OS and safety data and subgroup analyses were reported for the ENDEAVOR trial, which has previously reported significant improvements in PFS and OS with carfilzomib 56 mg/m² and dexamethasone versus bortezomib and dexamethasone in patients with relapsed/refractory MM; median follow-up durations for the respective arms were 44.3 months and 43.7 months. Compared with bortezomib plus dexamethasone, carfilzomib plus dexamethasone was associated with longer median OS duration (47.8 vs. 38.8 months; HR 0.76 [95% CI 0.633, 0.915]), a finding that was seen in age and cytogenetic subgroups, and according to number of prior lines of therapy, prior bortezomib or lenalidomide exposure and lenalidomide-refractory status. Exposure-adjusted adverse event incidences for the carfilzomib and bortezomib arms were 1352.07 and 1754.86 per 100 patient-years, with corresponding grade ≥3 adverse event rates of 162.31 and 175.90 per 100 patient-years.

Comment (DS): In this head-to-head study of two PIs, carfilzomib has emerged as the clear winner. The responses were deeper, the durations of response were longer and this translated into a clinically significant survival benefit. The benefit was seen in all subgroups, including low- and high-risk cytogenetics and whether patients had received prior bortezomib treatment or not. Carfilzomib was also better tolerated with exposure-adjusted adverse event rates significantly lower than with bortezomib treatment. There was less neuropathy than seen with bortezomib, but more hypertension and heart failure. The dose of carfilzomib used in this trial was 56 mg/m², which is the maximum dose where cardiovascular side effects are more common. While retreatment with bortezomib can be effective, it is not a replacement for carfilzomib in relapsed patients.

Multiple Myeloma Research Review

Impact of prior diagnosis of monoclonal gammopathy on outcomes in newly diagnosed multiple myeloma

Authors: Goyal G et al.

Summary: These researchers compared the prognosis of patients with MM with pre-MM diagnoses of monoclonal gammopathies (MGUS [monoclonal gammopathy of undetermined significance], smouldering myeloma or solitary plasmacytoma) to those without. The analyses included 2322 patients with MM; 774 were diagnosed with monoclonal gammopathies prior to MM and 1548 control patients had no pre-existing monoclonal gammopathy diagnosis. Median follow-up was 81 months. Compared with controls, patients with a pre-MM diagnosis of smouldering myeloma and those with a pre-MM diagnosis of solitary plasmacytoma had longer median OS durations (80 and 95 months, respectively vs. 56 months) and a lower risk of mortality (pooled HR 0.68 [95% CI 0.50, 0.93]), but there were no such differences between those with a pre-MM diagnosis of MGUS and controls.

Comment (DS): We generally think that transformed disease is a poor prognostic factor, so if a patient with a known indolent disease reaches the need for therapy they may do poorly. This study shows that is not the case. Delving deeper, smouldering myeloma that 'catches fire' actually has better survival than *de novo* myeloma. Previous work has shown that all myeloma starts as MGUS, so perhaps it is not surprising that MGUS patients have similar outcomes to *de novo* myeloma where there was no previous blood test.

VELCADE[®]
(bortezomib)

Look forward again

VELCADE (bortezomib). VELCADE is fully funded, Special Authority criteria apply. **Indications:** Untreated multiple myeloma unsuitable for high dose chemotherapy, in combination with melphalan and prednisone. Multiple myeloma, received at least one prior therapy, have progressive disease. As part of combination therapy, for induction therapy prior to high dose chemotherapy with autologous stem cell rescue for patients under 65 years of age with previously untreated multiple myeloma. **Dose and method of use:** 1.3 mg/m² may be administered intravenously at a concentration of 1 mg/mL as a 3-5s bolus injection or subcutaneously at a concentration of 2.5 mg/mL, see full Data Sheet for dosing schedule; reduce or withhold dose with haematological toxicity or neuropathy. Retreatment may be considered for patients who had responded to treatment with VELCADE; see full Data Sheet. VELCADE is for intravenous or subcutaneous use only. Intrathecal administration has resulted in death. **Contraindications:** Hypersensitivity to bortezomib, boron or mannitol. **Precautions:** DO NOT ADMINISTER INTRATHECALLY, peripheral neuropathy, hypotension, cardiac disorders, seizures, thrombocytopenia, gastrointestinal adverse events, pulmonary disorder, posterior reversible encephalopathy syndrome, seizures, tumour lysis syndrome, hepatic events, hepatic impairment, renal impairment, fertility, lactation, driving or operating machinery, pregnancy, lactation, children, frequently monitor Complete Blood Counts, see full Data Sheet. **Interactions with other drugs:** Inhibitors or inducers of CYP isozymes (in particular to CYP 3A4) eg ketoconazole, ritonavir, rifampicin, carbamazepine, phenytoin, phenobarbital, St John's Wort. Oral hypoglycaemics. Caution patients with concomitant medications that may be associated with peripheral neuropathy (such as amiodarone, anti-virals, isoniazid, nitrofurantoin, statins), or with a decrease in blood pressure. **Adverse events:** Infections, pyrexia, gastrointestinal disorders, haematological disturbances, peripheral neuropathy, hypotension, haematoma, headache, decreased appetite, general psychiatric disorders, dyspnoea, rash, blurred vision, vertigo, myalgia; fatigue, pyrexia, tumour lysis syndrome (uncommon), Stevens-Johnson Syndrome, toxic epidermal necrolysis, pulmonary disorders, intestinal obstruction, progressive multifocal leukoencephalopathy, very rare cases with unknown causality of John Cunningham (JC) virus infection resulting in PML and death, anaphylactic reaction, thrombotic microangiopathy, others, see full Data Sheet. **Presentation:** VELCADE is a Prescription Medicine containing bortezomib 1 mg or 3.5 mg per single dose vial. **Date of Preparation:** 13 November 2018. Please review full Data Sheet before prescribing, available at www.medsafe.govt.nz or on request from Janssen-Cilag (New Zealand) Ltd, PO Box 62185, Sylvia Park 1644, Auckland, New Zealand.
